NOTICES

REPORT NUMBERING SYSTEM - The numbering of technical project reports issued by the Naval Air Development Center is arranged for specific identification purposes. Each number consists of the Center acronym, the calendar year in which the number was assigned, the sequence number of the report within the specific calendar year, and the official 2-digit correspondence code of the Command Office or Functional Department responsible for the report. For example: Report No. NADC-73015-40 indicates the fifteenth Center report for the year 1973, and prepared by the Crew Systems Department. The numerical codes are as follows:

<u>CODE</u>	<u>OFFICE OR DEPARTMENT</u>
00	Commander, Naval Air Development Center
01	Technical Director, Naval Air Development Center
02	Program and Fiscal Management Department
03	Anti-Submarine Warfare Program Office
04	Remote Sensors Program Office
05	Ship and Air Systems Integration Program Office
10	Naval Air Facility Warminster
20	Aero Electronic Technology Department
30	Air Vehicle Technology Department
40	Crew Systems Department
50	Systems Analysis and Engineering Department
81	Administration Department

PRODUCT ENDORSEMENT - The discussion or instructions concerning commercial products herein do not constitute an endorsement by the Government nor do they convey or imply the license or right to use such products.

REPORT NO. NADC-73235-30

15 NOVEMBER 1973

NAVAIRDEVVCEN GRAPHITE-EPOXY COMPOSITE WING
FOR BQM-34E; STRESS AND VIBRATION ANALYSIS

FINAL REPORT

AIRTASK NO. A320000/001B/4F41422206
WORK UNIT HJ 202

A weight saving of 54 percent has been achieved in the in-house design and fabrication of a composite wing for the BQM-34E aerial target vehicle. Design criteria are identical to those of the 5g production metal wing. Results of the stress analyses indicate adequate margins of safety.

INTRODUCTION

The Naval Air Development Center (NAVAIRDEVVCEN) has recently completed the design, analysis, fabrication and static testing of a graphite-epoxy composite wing for the unmanned BQM-34E aircraft. A weight saving of 54 percent has been achieved while meeting all static strength and static and dynamic aeroelastic requirements.

The BQM-34E is a high-altitude, supersonic, recoverable aerial target vehicle. The wing has a 9-foot span and an aspect ratio of 2.5. Other dimensions are shown in Figure 1. The main panel of the production design consists of chem-milled stainless steel skins bonded to an aluminum honeycomb core. The outboard panels are made of fiberglass-reinforced plastic. With the exception of the outboard panels, the entire wing is factory-assembled by adhesive bonding and riveting. Its total weight is 157 pounds, about 30 percent of the structural weight of the aircraft.

In the composite wing design, emphasis was placed on reducing the weight and the number of major subassemblies while maintaining the original airfoil shape and planform. The development was initiated under Independent Research (reference (a)) as an in-house effort whose objectives were to exploit the improved material properties of advanced filamentary reinforced composites, to obtain an optimum design with minimum weight and to allow acquisition of service experience on a primary structural component of a high performance vehicle with no risk to human life. The final design, analysis, fabrication and testing of the wing were carried out entirely in-house under reference (b). Following the successful static testing at NAVAIRDEVVCEN, flight testing commenced at the Naval Missile Center (NAVMISCEN), Point Mugu, Ca.

Results of static and flutter analyses of a preliminary wing design have been reported previously in references (c) and (d). The static aeroelastic and flutter analyses and static test of the final design are described and their results presented in references (e) and (f). This report presents the procedure and results of the final stress and vibration analyses and includes the following:

- a. composite and core material characteristics including material stiffness properties and allowable stresses;
- b. descriptions of the wing structure and the finite element model used for the analyses;
- c. results of the stress and vibration analyses;
- d. computation of critical stresses and margins of safety for the skins and core.

DESIGN CRITERIA

The flight conditions for the composite wing are the same as for the production metal wing, and are described in reference (g), in which the critical flight conditions and the resulting shear, torque and bending loads are presented. The equivalent static test loads are specified in reference (h).

The exposed planform and aerodynamic profile of the composite wing are identical to those of the metal wing. Size and location of fuselage attachment bolts are the same to allow installation of the wing without modification of the fuselage. In addition, the maximum airfoil section depth is limited to 1.62 inches. Finally, to facilitate manufacture, reduce vulnerability to accidental damage, and maintain balance of the laminate, the minimum composite skin thickness has been set at five plies (0.030 in.).

Sufficient stiffness of the wing is required to preclude static and dynamic aeroelastic instabilities throughout the flight envelope. A discussion and analyses of these effects are contained in reference (e).

Stiffness and strength properties of the unidirectional graphite-epoxy material and of the several laminate constructions used in the wing, as well as those of the core materials are listed in Table I. Since, in general, advanced composites exhibit little static yielding, strength calculations for the laminated skins are based solely on ultimate stresses. For the unmanned aircraft, ultimate loads are 25 percent over limit.

DESCRIPTION OF WING STRUCTURE

The principal features of the composite wing construction are shown in Figure 2. Laminated graphite-epoxy skins, varying in thickness from 5 to 30 plies (.030 to .180 in.), are adhesive bonded to the aluminum honeycomb core. The laminate construction varies over the planform. The number of plies of each orientation is varied to meet local stiffness and strength requirements and to maintain balanced construction. In the center section and in the outboard two-thirds of the exposed span, the core density is 4.5 lb./ft.³. Inboard, where shear loads are higher, and particularly in the vicinity of the attachments, higher density core materials (6.1, 8.1 and 23.0 lb./ft.³) are used. The leading edge is a molded solid section of chopped fiber covered by a four-ply, ±45° laminated skin.

To close out the center section and the fuselage interface, and to distribute the attachment bolt reaction loads, channel sections of ±45° construction are placed in the core. Attachment bolt loads are transferred to the adjoining structure by means of titanium flanges bonded

inside the skins and spool-shaped aluminum fittings inserted into the core. Across the aft end of the center section, where the bending moment is highest and the attachment bolt load is most critical, the graphite-epoxy laminated skins are replaced by titanium plates, step-lap bonded to the adjoining laminates. Finally to accommodate electrical wiring for the wing tip antenna, a fiberglass conduit is enclosed within the core between the forward edge of the center section and the wing tip, where mounting holes for the tip antenna pod are provided.

FINITE ELEMENT MODELLING AND ANALYSIS

A diagram of the finite element model assembled for analysis using NASTRAN is shown in Figure 3. Triangular and quadrilateral orthotropic plate elements are used to represent the skins and core. The stiffness (bending and transverse shear) and mass properties of each element are derived from the local laminate construction, number of plies, core properties, and the airfoil thickness. The remaining structural elements - leading edge, conduit, channel section ribs and tip antenna pod - are represented by bar elements. In order to accurately simulate the mass distribution of the wing for the vibration analysis, additional lumped masses are placed along the leading edge and tip. A listing of the NASTRAN bulk data deck is reproduced in Appendix A.

For the static analysis, the test loads from reference (h) were distributed over the finite element model as concentrated forces applied to the grid points. To simulate the boundary condition for the critical load condition (5g symmetric pull-up), vertical displacements were constrained for the grid points located at the fuselage attachment bolts, and rotations about the longitudinal axis were constrained along the aircraft center line. The results of the static analysis, including the deflected shape, deflections at selected points, and reaction loads are shown in Figure 4 and Tables II and III. A complete listing of the NASTRAN output data is reproduced in Appendix B.

To provide vibration frequency and mode data for the modal flutter analysis described in reference (e), the real eigenvalue analysis option available in NASTRAN was used. Both symmetric and antisymmetric modes were computed by altering the constraints at the fuselage centerline. Similar frequencies, generalized masses and generalized stiffness resulted for the two cases. These data are listed in Table IV for the first five modes of each case. The mode shapes of the first three symmetric modes are shown in Figures 5, 6 and 7, and of the first three antisymmetric modes in Figures 8, 9 and 10. A complete listing of the NASTRAN output data for the symmetric modes is reproduced in Appendix C.

STRESS ANALYSIS

To determine the ply stresses in the graphite-epoxy skins, element stresses computed by NASTRAN are first transformed into the local laminate coordinates. The stresses in laminate coordinates are shown for two streamwise sections in Figures 11 and 12. Laminate stiffness properties are used to calculate the resulting strains, which are subsequently transformed for each of the ply orientations of the local laminate construction. Unidirectional material stiffness coefficients are then used to compute the ply stresses. To account for the combined-stress state of the material in determining margins of safety, the interaction formula below is applied:

$$\left(\frac{\sigma_1}{X_1}\right)^2 + \left(\frac{\sigma_2}{X_2}\right)^2 + \left(\frac{\sigma_6}{X_6}\right)^2 - \frac{\sigma_1 \sigma_2}{X_1 X_2} = R_o^2$$

$$\left| \frac{\sigma_i}{X_i} \right| = R_i \quad i=1,2,6 \quad \text{Ult. M.S.} = \frac{1}{1.25 \times R_{\max}} - 1.$$

where $\sigma_1, \sigma_2, \sigma_6$ are the inplane normal and shear stresses in the ply and X_i are the allowable stresses. The margin of safety of the element is the lowest of the margins for the individual ply orientations. The critical elements of the finite element model and the stresses and margins of safety resulting from the static analysis are listed in Table V.

Depending upon the ratio of the skin thickness to the section depth ($0. \leq t/H \leq 0.5$) the core shear stress varies from 1.0 to 1.5 times the average shear stress (force/area), but may be conservatively approximated by the relation

$$\tau \leq \frac{1}{H} \left(1 + 1.15 \frac{t}{H} \right) \times \text{shear force per unit width}$$

To determine the core shear stresses and margins of safety, the element shear forces (per unit width) from NASTRAN and the skin thickness and section depth at the element centroid are used in the formula above. The resulting stresses are transformed into the ribbon and transverse directions of the core, and the strength criterion below is applied:

$$\frac{\tau_L}{x_L} + \left(\frac{\tau_w}{x_w} \right)^{1.575} = R''$$

$$\text{Ult. M. S.} = \frac{1}{1.25 \times R''} - 1.$$

where the subscripts L and W refer to the ribbon and transverse directions respectively. Shear stresses and margins of safety for the critical elements of the model are shown in Table VI.

The minimum ultimate margins of safety calculated for skins and core are 0.14 and 0.32 respectively. Therefore, the wing is considered safe for flight.

CONCLUSIONS

1. Based on the static aerodynamic loads prescribed, adequate margins of safety have been provided for the skins and core of the graphite-epoxy composite wing designed and fabricated for the BQM-34E target vehicle.
2. Static and dynamic aeroelastic (flutter) analyses, reviewed in reference (e), indicate that the stiffness and mass distribution of the composite wing are sufficient to avoid any instabilities throughout the flight envelope.

13. ABSTRACT <p>A weight saving of 54 percent has been achieved in the in-house design and fabrication of a composite wing for the BQM-34E aerial target vehicle. Design criteria are identical to those of the 5g production metal wing. Results of the stress analyses indicate adequate margins of safety.</p>
